## Specification

### Title of Invention

Fuel Supply Control Variable Cylinder System

### Claim(s)

1. A fuel supply control type variable cylinder system for multi-cylinder engines equipped with a fuel supply system and a variable cylinder control circuit that permit partial cylinder operation by shutting off the supply of fuel to a specified group of cylinders from the fuel supply system depending on engine load, comprising a three-way catalyst and a first oxygen sensor located in the exhaust passage of the active cylinder group; a three-way catalyst and a second oxygen sensor located in the merged passage where the exhaust passage of the inactive cylinder group meets the downstream of the exhaust passage mentioned above; a selection circuit that selects the output of the first oxygen sensor under partial cylinder operation or the output of the second oxygen sensor under full cylinder operation depending on shut-off of the variable cylinder system circuit mentioned above; a temperature detection means that detects the temperature of the three-way catalyst in the merged passage; and an air-fuel ratio control circuit in which the fuel supply signal mentioned above terminates the shut-off operation when the temperature detection means detects that the temperature is below a specified value, while interrupting the air-fuel ratio control that controls the fuel supply signal in such a manner so as to make the air-fuel ratio become equal to the stoichiometric value.
2. The fuel supply control type variable cylinder system described in claim 1, a unique feature of which is that the temperature detection means mentioned above represents a circuit that determines the temperature by detecting that one portion of said fuel supply signal is shut off and that the output of the second oxygen sensor is higher than a specified value.

### Detailed Explanation of the Invention

This invention concerns a fuel supply control type variable cylinder system engine equipped with a three-way catalyst in the exhaust system to feedback-control the air-fuel ratio; in particular, a system in which degradation of the exhaust emission control operation is prevented by resuming the full cylinder operation whenever the catalyst temperature decreases.

Generally speaking, engine fuel economy tends to improve when the engine is operated under a heavy load condition. This is the reason the variable cylinder engine concept was developed for multi-cylinder engines to stop the fuel supply to one group of the cylinders under a light engine load so that the relative load per each of the remaining cylinders can be increased leading to improved fuel economy under light load conditions.

On the other hand, from the standpoint of exhaust emission control measures, there is a well known system in which a three-way catalyst is installed in the engine exhaust system, upstream of which an exhaust sensor (oxygen sensor) is installed. In this system, the air-fuel ratio is feedback-controlled to become approximately equal to the stoichiometric value based on the output of this exhaust sensor in order to achieve high efficiency oxidation of HC and CO concurrently with reduction of NOx.

When this air-fuel ratio control system is employed with a variable cylinder engine, when a cylinder

group is inactive, the air exhausted from these inactive cylinders is mixed with the combustion exhaust gas from the active cylinders before it passes through the oxygen sensor and the three-way catalyst. This results in oxygen sensor output that indicates an oxygen rich condition so the feedback control forces the system to make the air-fuel ratio extremely lean, which in turn tends to degrade fuel economy.

One measure to address this problem is to install oxygen sensors and three-way catalysts in the exhaust passage of the cylinders that are always active as well as in the merged exhaust passage in which the exhaust passages from the active cylinders and inactive cylinders are joined. When one portion of the cylinders is inactive, feedback control is performed based only on the output of the oxygen sensor through which the exhaust gas from the active cylinders passes making the air-fuel ratio of the combustion exhaust gas approximately equal to the stoichiometric value. In this manner, the system can achieve good fuel economy and emission control at the same time.

There is, however, a problem during the engine warm-up period or during the time when the partial cylinder operation lasts a long time. The exhaust gas temperature tends to become low under these conditions, especially the temperature of the downstream three-way catalyst. It undergoes a large-scale decrease from its normal activated condition resulting from the entry of exhausted air from the inactive cylinders.

When the engine resumes full cylinder operation after the decrease in catalyst temperature, it is difficult to achieve good reaction at the downstream three-way catalyst which results in partial degradation of its exhaust emission control performance. This phenomenon tends to occur when a vehicle starts climbing uphill after it has been driven on a gently sloping downhill under the partial cylinder mode for a long time.

In order to eliminate this type of problem, there have been measures such as installing temperature sensors in the three-way catalyst in the exhaust passages. Whenever these temperature sensors detect a decrease in catalyst temperature below a specified value, the variable cylinder control system mode is interrupted to restore the full cylinder mode and expedite a quick increase in catalyst temperature. This measure, however, requires special temperature sensors and, inevitably, leads to cost escalation.

There is another measure in which a low engine temperature condition is detected by the engine coolant temperature and interrupting the variable cylinder control system. However, this system is still unable to solve the problem when the full cylinder operation is resumed, and tends to lower engine response characteristics.

Moreover, in the air-fuel ratio feedback control system mentioned above, similar to the three-way catalyst, the output characteristics of the oxygen sensors also tend to fluctuate and deviate from the proportionality with respect to the oxygen concentration when its temperature is decreased, resulting in impairment of the feedback control accuracy.

In order to address this problem, a normal procedure is to "clamp" the feedback signal to maintain the air-fuel ratio at a fixed value so that feedback control of the air-fuel ratio can be temporarily interrupted when the temperature estimated from the output of the oxygen sensor is determined to be below a specified value.

Based on such background, this invention is designed to assure the exhaust emission control performance

of a variable cylinder engine to control the air-fuel ratio based on the output of the oxygen sensor, which is located near the exhaust inlet of the three-way catalyst for the partially active cylinders, and which has similar temperature characteristics as those of the three-way catalyst temperature. When the downstream oxygen sensor temperature decreases below a specified value, feedback control of the air-fuel ratio is interrupted while at the same time the variable cylinder control system operation is also interrupted to restore full cylinder operation. With this method, the three-way catalyst temperature can be quickly increased by the combustion exhaust from all cylinders to prevent a decrease in the three-way catalyst temperature so that the good exhaust emission control operation can be maintained. The purpose of this invention is to introduce a fuel supply type variable cylinder engine that will achieve the performance explained above.

Next, a working example of this invention is presented using illustrations.

Number 1 represents the engine body, while f1 - f3 are inactive cylinders, the operation of which is stopped during the light load condition as explained later, and f4 - f6 are cylinders that are always active. Numbers 2a - 2f represent fuel injection valves installed in the intake ports of these cylinders, while 3 is an intake pipe, 4 a throttle valve, 5 an intake air flow sensor, and 6a and 6b are exhaust pipes for cylinder groups f1 - f3 and f4 - f6, respectively. 7 is a three-way catalyst installed in exhaust pipe 6b, and 8 is an oxygen sensor installed near the inlet of this three-way catalyst. 9 is a three-way catalyst installed in a merged pipe, 6, between exhaust pipes 6a and 6b, while 10 is an oxygen sensor installed near the inlet of three-way catalyst 9.

As described later, the air-fuel ratio control circuit, 12, receives the output of oxygen sensors 8 and 10 as input through a selection relay, 11, that performs the switching action based on the signal from a variable cylinder control circuit, 16, which is explained later. As depicted in Fig. 2, air-fuel ratio control circuit 12 is comprised of a comparator, 13, which compares the sensor output with the comparison standard voltage; a standard voltage setting device, 14, that outputs standard voltage corresponding to the stoichiometric air-fuel ratio; a correction waveform generation circuit, 16, that receives base pulses from a terminal, 15; a low catalyst temperature detector, 17, that detects the low temperature condition of oxygen sensor 10; and a clamp circuit, 20, which clamps (sets the air fuel ratio feedback valve at a specified value irrespective of the outputs of oxygen sensors 8 or 10) the feedback control value by receiving the low temperature signal from detector 17, and by receiving the full-throttle signal at the time of a fully open output and the fuel-cut signal at the time of deceleration from terminals 18 and 19.

A fuel injection control circuit (EGI circuit), 15, determines the amount of fuel injection based on the air-fuel ratio control signal from air-fuel ratio control circuit 12, and the signals from intake airflow sensor 5 and rpm sensor 21. Although the output of the EGI circuit is applied directly to fuel injection valves 2d - 2f, it is applied to other fuel injection valves 2a - 2c through a variable cylinder control circuit (VCS circuit, hereafter), 16. When a light load condition is detected by this VCS circuit 16, the fuel supply to fuel injection valves 2a - 2c is shut off making cylinders f1 - f3 inactive. At the same time, the system is designed such that selection relay 11 is switched to the side of oxygen sensor 8, which is exclusively provided for active cylinders f4 - f6 by the same signal generated by the VCS circuit 16 to decrease the

number of cylinders.

In principle, VCS circuit 16 is designed so as not to send the fuel injection pulse signal from EGI circuit 15 to fuel injection valves 2a ~ 2c during light load conditions making cylinders f1 ~ f3 inactive so that the fuel economy can be improved during light load conditions. The basic configuration is comprised of pulse comparators, 22 and 23, for the fuel injection signal having a pulse width proportional to engine load; pulse width setting devices, 24 and 25, that output the pulse setting values ( $W_H$ ) and ( $W_L$ ) corresponding to the heavy and light load conditions as comparison standard values; an engine rpm comparator, 26; an rpm setting device, 27, that makes the specified low rpm setting ( $N_0$ ) be the standard value; a flip-flop, 30, that sends the outputs from an "OR" circuit, 28, and an "AND" circuit, 29, to "set input (S)" and "reset input (R)" respectively; an "OR" circuit, 31, that inputs the output of this flip-flop 30 and the low temperature detecting device 17 of the air fuel ratio control circuit 12 mentioned above; and an "AND" circuit, 32, that receives the outputs of "OR" circuit 31 and EGI circuit as its inputs. In other words, since low temperature detecting device 17 is connected to the input side of "OR" circuit 31, the circuit is configured such that the partial cylinder deactivation command from VCS circuit 16 is cancelled when the temperature of oxygen sensors 8 and 10 is low.

Next, the operation of this invention is explained. Fig. 3 shows when engine rpm ( $N$ ) and fuel injection pulse width ( $W$ ) are in the 6-cylinder operation region. In this condition, as explained later, the output level of flip-flop 30 in the VCS circuit 16 becomes "1," and cylinders f1 ~ f3 are in the active condition, in other words, the system is in the full cylinder mode. After this, selection relay 11 is energized by receiving the output of "OR" circuit 31, which is "1" to perform the switching action, and the output of oxygen sensor 10, which detects the exhaust temperature of all cylinders, is input to air-fuel ratio control circuit 12. The output of comparator 13, which compares the oxygen concentration in the exhaust gas with the standard value corresponding to the stoichiometric air-fuel ratio generated by standard setting device 14, is fed back to EGI circuit 15 through clamp circuit 20 after it detects the deviation signal from the standard pulse at correction waveform generation circuit 16. Through these steps, the air-fuel ratio converges approximately to the stoichiometric value so that three-way catalyst 10 (*sic*) can function correctly. When the engine enters the light load condition, causing pulse width ( $W$ ) and engine rpm ( $N$ ) to shift to the 3-cylinder region indicated in Fig. 3, the output level of flip flop 30 becomes "0" and the operating condition of cylinders f1 ~ f3 becomes inactive. At this time, since low temperature detector 17 outputs the signal "0" indicating that oxygen sensor 10 is not at a temperature below the specified value, the output of "OR" circuit 31 becomes "0," closing the gate of "AND" circuit 32. At the same time, selection relay 11 is de-energized by the output "0" of "OR" circuit 31, and is switched over to the oxygen sensor 8 side as indicated in Fig. 2 so that the system is controlled in such a way that three-way catalyst 7 in the active cylinder group side consisting of cylinders f4 ~ f6 can exhibit high conversion efficiency.

When this partial cylinder operation condition continues for a long time, or during the engine warming-up period, the exhaust gas temperature entering the catalyst decreases. If the temperature becomes so low that catalyst 9 and oxygen sensor 10 can no longer function properly, low temperature detector 17 outputs

the level "1" signal to force the feedback signal to assume the "clamp" condition through clamp circuit 20. When the "clamped" signal value is applied to EGI circuit 15, the air-fuel ratio is controlled to hold at a specified fixed value. In this case, however, the control accuracy becomes slightly lower than in the case of feedback control, resulting in the situation that the function of three-way catalyst 9 tends to become degraded. In order to end this condition as quickly as possible, it is best to resume full cylinder operation. To comply with this requirement, in this invention, the output of low temperature detector 17 is input to "OR" circuit 31 to make cylinders f1 ~ f3 active whenever the low temperature detection signal (level "1" signal) is output, regardless of the output level of flip-flop 30. As a result of this forced restoration of full cylinder operation, when the exhaust temperature increases gradually to restore the function of three-way catalysts 7 and 10 (sic), and as long as the engine is in the light load condition during this period, the system is switched back to the 3-cylinder operation mode, provided that the clamp signal is retracted.

Next, the operation of VCS circuit 16 is briefly described here. Since the output of EGI circuit 15 is directly applied to fuel injection valves 2d ~ 2f for cylinders f4 ~ f6, the cylinder group consisting f4 ~ f6 is always in the active state. Although other cylinders f1 ~ f3 are in the active state as long as "AND" circuit 32 gate is open, they assume the inactive state when the output level of flip-flop 30 becomes "0" and low temperature detector 17 is not generating the detection signal (output of "0"). In other words, when the detection signal is output, cylinders f1 ~ f3 retain the active state even when the output level of flip-flop is "0." Moreover, the output level of flip-flop 30 becomes "1" when pulse width (W) is greater than the standard ( $W_g$ ) or when rpm (N) is lower than the standard value ( $N_0$ ) (the 6-cylinder region in Fig. 3), and it becomes "0" when pulse width (W) becomes lower than the standard ( $W_g$ ) and rpm (N) becomes higher than the standard ( $N_0$ ) (the 3-cylinder region in Fig. 3). Since the "set" input terminal of flip-flop 30 is connected to "OR" circuit 28, and the "reset" input terminal of flip-flop 30 is connected to "AND" circuit 29, the region indicated by "maintain the same number of cylinders" in Fig. 3 is formed.

As explained above, according to this invention, it is possible to always maintain a high catalytic conversion efficiency of the three-way catalyst since the variable cylinder control is interrupted when the oxygen sensor is at the temperature condition under which it does not function properly, and full cylinder operation is maintained even under the light load condition to achieve a rapid temperature increase in the entering exhaust gas to restore the three-way catalyst function. Compared with the system in which variable cylinder control is performed by detecting engine coolant temperature, since in this invention variable cylinder control is performed by detecting the low temperature condition of the oxygen sensor that is sensitive to temperature change, it is possible to obtain accurate controls having good response characteristics. Another effect is that the system configuration is not complicated and is less expensive.

#### Brief Explanation of Figures

The figures show one working example of this invention. Figure 1 is a simplified configuration diagram of the overall system, Fig. 2 is a block diagram of the control system, and Fig. 3 explains the variable cylinder control pattern.

燃料供給気流制御装置

特許請求の範囲

1. 燃料供給量を制御する燃料供給装置と、燃料供給装置からの所定の気流をグループへの燃料供給管とエンジン負荷に応じて調節して燃料供給量とする燃料供給制御回路とを備えた燃料エンジンにおいて、燃料供給グループの燃料通路に設けた三元触媒と第1の酸素センサと、上記燃料通路の下流の休止通路の燃料通路との合流通路に設けた二元触媒と第2の酸素センサと、上記燃料供給制御回路の基端に於いて燃料供給通路時は第1の酸素センサの出力を、燃料供給通路時は第2の酸素センサの出力を選択する選択回路と、合流通路の二元触媒の温度を検出する温度検出手段と、前記温度検出手段が所定温度以下を検出した時に上記燃料供給回路が調節を中止すると共に、燃料比が濃燃状態になるとように上記燃料供給量を制御する燃料比

制御を中止する燃料比制御回路とを備えたことを特徴とする燃料供給気流制御装置。

2. 上記温度検出手段は、上記燃料供給管の一端が設けられ、且つ第3の酸素センサの出力が所定値以上であることを検出して温度を制御する回路であることを特徴とする特許請求の範囲第1項記載の燃料供給気流制御装置。

発明の詳細な説明

本発明は燃料系に三元触媒を備えて濃燃を日係にフィードバック制御する装置を備えた燃料供給気流制御エンジンに関し、とくに、燃料供給の低下したときには必ずしも燃料供給に使用されることにより、燃料消費化作用を低下せまいようにした装置を提供するものである。

一般にエンジンを高い負荷状態で運転すると燃料消費が増える傾向があり、このため多量にエンジンにおいて、エンジン負荷の小さいときにも燃料供給グループに於ける燃料の供給を停止し、残りの燃料供給の単位時間当たりの負荷を相対的に高め、燃料消費の損失を改善するようにした装置

歌初舞マソリンが考えられた。

一方、エンジンの排気対策のため、排気系に三元触媒を設置するとともに、その上流に排気センサ（酸素センサ）を設置し、このセンサ出力とともに排気比を圧縮率・空燃比となるようにフィードバック制御し、三元触媒による $\text{HC}$ 、 $\text{CO}$ の酸化と $\text{NO}_x$ の還元を共に効率よく行わせるシステムが知られている。

供給する空気量制御回路16からの信号により切替動作する選択リレー11を介して酸素センサ8、10の出力が選択的に入力される空気比コントロール回路12は、第2図に示すようにセンサ出力を比較基準電圧と比較する比較器13、運転空気比に相当する基準電圧を出力する基準電圧発生器14、端子15より基本パルスを受ける補正電圧発生器16、酸素センサ10の低濃状態を検出する触媒装置故障検知器17、この検知器17からの低濃信号を端子18、19からの全開出力時のフリップフロップスリプナ信号と吸気時のフリップフロップ信号を受けてアイドストップ制御をクランブ（吸気

センサ8又は10の出力値に比例せしめ空気比アイドストップ値を所望値に固定する）するクランブ回路20とで形成される。

空気比コントロール回路12からの空気比制御信号と、吸入空気量センサ5、送風機モータ21とからの信号に基づいて燃料噴射量を決定する燃料噴射制御回路（BQI回路）15の出力は、燃料噴射弁22~25に対しては直接印加されるが、他の燃料噴射弁26~28へは送風機制御回路（以下VCS回路）16を介して印加される。このVCS回路16で燃料噴射量を制御すれば、燃料噴射弁22~28への燃料供給はカットされ、気筒1~4は休止状態になる。また同時にVCS回路16の上記制御量の減少指令により、選択リレー11は燃料気筒4~6に専用の酸素センサ8個に切り換えられるようにになっている。

VCS回路16はBQI回路15からの燃料噴射バルブ信号を基準として発生時には燃料噴射弁22~28へ送らないようにして気筒1~4を休止状態にするもので、燃料噴射弁22~28

触媒等の故障をならめとする。その基本的構成は、原則として燃料噴射に比例したパルス値をもつ燃料噴射信号のパルス幅比較器22、23、失火検出器と高負荷に対応したパルス幅検定値（ $W_b$ ）、（ $W_L$ ）を比較基準値として出力するパルス幅検定器24、25、エンジン回転数比較器26、一定の低回転数検定値（ $N_0$ ）を基準値にする回転数検定器27、そしてOK回路28とAND回路29の出力をセット入力（S）とリセット入力（R）とするフリップフロップ30、このフリップフロップ30と上記空気比コントロール回路12の低濃検知器17との出力を入力とするOR回路31、OR回路31とBQI回路15の出力を入力とするAND回路32とからなる。つまり、OR回路31の入力側に低濃検知器17を接続するため、酸素センサ8、10が低濃のときには、VCS回路16の一部燃料噴射指令を付与する回路構成にしている。

次に本発明の作用を説明する。まずエンジン回転数（ $N$ ）と燃料噴射パルス幅（ $W$ ）が第3図に示された3段階領域にあるときは、通常であるようにV

CS回路16のフリップフロップ30の出力レベルは"1"となり、気筒1~4を運転状態にする、即ち全気筒運転を行う。これに伴いBQI回路15の出力"1"を受けて選択リレー11が動作して切替動作し、全気筒の排気流量を検出する酸素センサ10の出力が空気比コントロール回路12に入力する。排気中の酸素濃度を運転空気比に対応する基準電圧14の基準値と比較する比較器13の出力は、補正電圧発生器16において基本パルスとの偏差信号を放出し、クランブ回路20を通過してBQI回路15へフィードバックされる。これによつて三元触媒10が適正に機能するように空気比が適正値を維持されるのである。ここで検出が異常状態になり、パルス幅（ $W$ ）とエンジン回転数（ $N$ ）が第3図の3段階領域に移行すると、フリップフロップ30の出力レベルは"0"となり気筒1~4を休止状態にする。なおこのとき低濃検知器17は酸素センサ10が所定値以下の低濃状態でないという信号、即ちレベル"0"を出力しているために

OR回路21の出力は“0”となり、AND回路22のゲートを閉じる。同時にOR回路21の出力“0”により選択リレー11は励磁が解かれて、第2図に示す如く、取巻センサ8電圧に切り換え、取巻機用アループ4-4-6側の二次電圧7が高い駆動効率を発揮するようにコントロールする。

ところで、この一風筒停止状態が長く続いたり、あるいは駆動速度時は放熱流入熱風温度は低下する。いまだ熱センサ10が高温を出力を発揮しえない程度に低下になると、低風速制御17がレベル“1”を出力してクランプ回路20を介してフィードバック信号をクランプ回路20に与え、クランプされた信号がOR回路15に付加されると、取巻比に所定の固定値に保持されるように制御されるが、この場合だけ、フィードバック制御に比べて速度が若干低下するから、三元触媒の機能は低下しがちになる。このような状態からでもできるだけ早く抜け出すためには全風筒運転に戻すことが好ましく、そこで本発明は低風速制御17の出力をOR回路31に入力し、フリフ

フアンプ30の出力レベルに依存なく、低風速時の検出信号(レベル“1”)を出力したときは、取巻比1-4-6を駆動状態にする。このようにして全風筒運転に強制的に復帰させた結果、排気温度が次第に上昇して三元触媒7、10の機能が回復すると、フリフアンプ信号の解除を条件として、このとき駆動状態を再び3風筒運転に切り換わるのである。

ここでVCS回路16の作用を簡単に説明すると、ROI回路18の出力が取巻比4-4-6の燃料供給弁2-21に対しては直接的に印加されるために、この取巻比アループ4-4-6は常時駆動状態にある。他の取巻比1-4-6はAND回路22のゲートが開いていないかいは駆動状態になるが、フリフアンプ30の出力レベルが“0”で、かつ低風速制御17が検出信号を無しでないとき(出力は“0”)に停止状態になる。減速すると、検出信号が出力されているときは、フリフアンプ30の出力レベルが“0”でも取巻比1-4-6は駆動状態を維持する。セカンダリアンプ

プ30の出力レベルはレベル信号値(W)が基準値(WN)以上か又は取巻比(N)が基準値(NO)以下の場合(第3図の6気筒領域)には“1”になり、レベル値(W)が基準値(WN)以下で、かつ取巻比(N)が基準値(NO)以上の場合(第3図の3気筒領域)には“0”になる。フリフアンプ30のセント入力端子をOR回路28に、リセット入力端子をAND回路29に接続したため、第3図の取巻比保持の領域が形成される。

以上のようにな発明によれば、取巻センサが適正に作動しない低風速状態のときは低風速制御を停止し、たとえ取巻機時でも全風筒を駆動状態に保ち、速やかに放熱流入熱風温度の上昇を促して三元触媒の機能を回復させるので、常に高い駆動効率を維持することができ、また低風速制御を強制冷却水を感知して行なうのに比べ、温度変化に敏感な取巻センサの低風速状態を検知して行なうため、その応答性が良好で運転の制御が得られ、また、運転が安定化セパ容易になる効果を有する。

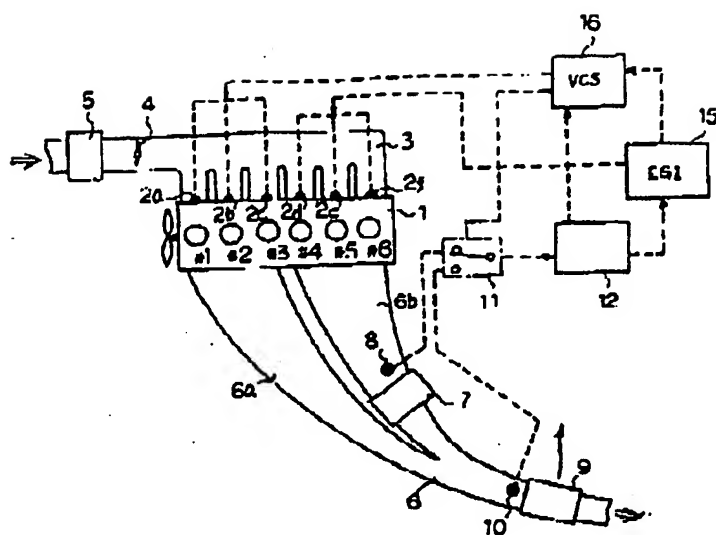

#### 図面の簡単な説明

図面は本発明の実施の一例を示すもので、第1図は概略構成図、第2図は取巻比のアロケ図、第3図は取巻比制御パターンを説明図である。

#### 2. 補正の内容

- 1) 明細書第1頁乃至第2頁の「特許請求の範囲」を次のように補正する。

##### 「特許請求の範囲」

1. 燃料供給装置を制御する燃料供給装置と、前記燃料供給装置からの所定の燃料供給グループへの燃料供給量をエンジン負荷に応じて調節して部分負荷に適合する燃料供給制御装置とを備えた多気筒エンジンにおいて、燃料供給グループの所定値に設けた三元触媒と第1の燃費センサと、上記燃料供給の下流の排気管の所定値に設けた三元触媒と第2の燃費センサと、上記燃料供給の制御装置の調節に応じて部分負荷に供給する第1の燃費センサの出力を、全負荷運転時は第2の燃費センサの出力を優先する選択回路と、各気筒毎の三元触媒の温度を検出する温度検出手段と、前記温度検出手段が所定温度以下を検出し、かつ、上記燃料供給装置の調節を中止すると共に、空燃比が燃焼空燃比になるように

上記燃料供給量を制御する空燃比制御を中止する空燃比制御回路とを備えたことを特徴とする燃料供給装置制御装置。

2. 上記温度検出手段は、上記燃料供給装置の一端が燃焼され、且つ第2の燃費センサの出力が所定値以上であることを検出して温度を判別する回路とを備えることを特徴とする特許請求の範囲第1項記載の燃料供給装置制御装置。
